# EN530.603 Applied Optimal Control
## Homework #2

September 21, 2018

Due: September 26, 2018 (before class)

Prof: Marin Kobilarov

1. Find the curve $x^*$ that minimizes

$$J(x) = \int_0^1 \left( \frac{1}{2}\dot{x}^2(t) + 3x(t)\dot{x}(t) + 2x^2(t) + 3x(t) \right) dt$$

and passes through the points $x(0) = 0$ and $x(1) = 4$.

2. Find the extremals for

$$J(x) = \int_0^{t_f} [\dot{x}_1^2(t) + \dot{x}_2^2(t) + 3x_1(t)x_2(t)]dt,$$

with

a) $x_1(0) = 0$, $x_2(0) = 0$, $t_f = 1$, $x_1(t_f)$ free, $x_2(t_f) = 1$.

b) $x_1(0) = 0$, $x_2(0) = 0$, $t_f$ free, $x(t_f)$ must lie on the surface

$$x_1(t) + 3x_2(t) + 5t = 15$$

Note: the last constraint is of the general form $\psi(x(t_f), t_f) = 0$. See last section in Lecture#4 posted on the website for details.

3. (Kirk 4-5.) Let $\eta$ be a continuously differentiable function of time $t$ that is arbitrary on the interval $[t_0, t_f]$ except at the end-points where $\eta(t_0) = \eta(t_f) = 0$. If $\epsilon$ is an arbitrary real parameter, then $x^* + \epsilon\eta$ represents a family of curves. Evaluating the functional

$$J(x) = \int_{t_0}^{t_f} g(x(t), \dot{x}(t), t)dt$$

on $x = x^* + \epsilon\eta$ makes $J$ a function of $\epsilon$, and if $x^*$ is an extremal this function must have a relative extremum at $\epsilon = 0$.

Show that the Euler-Lagrange equations can be equivalently obtained from the necessary condition

$$\left.\frac{dJ(x^* + \epsilon\eta)}{d\epsilon}\right|_{\epsilon=0} = 0.$$

Note: upload your code using the File Upload link on the website. In addition attach a printout of the code and plots to your homework solutions.
